

A Convenient Preparation of Acetone Solutions of Dimethyldioxirane

Waldemar Adam*, Joachim Bialas, and Lazaros Hadjirapoglou¹⁾

A novel simplified procedure affords consistently 0.09–0.10 M solutions of distilled dimethyldioxirane in acetone; other than

control of the reaction temperature below 15°C and vigorous mechanical stirring, no other precautions are mandatory.

The importance of isolated dimethyldioxirane (Eq. 1) for preparative oxidation chemistry, as witnessed by the surge of activity²⁾ since its isolation³⁾ in 1985, demands a convenient method of isolation of this efficient oxidant. Presently, we provide a much simplified version of a recently reported procedure⁴⁾, which should be of general interest and utility.

Key features of the new version are that even normal water (not distilled from EDTA) and commercial-grade acetone (directly from the metal canister) can be employed, that the high-efficiency condenser⁵⁾ is not necessary, and that the reaction can be conducted under a normal atmosphere. Important in the revised procedure is to control rigorously the reaction temperature below 15°C and stir efficiently. In this manner routinely ca. 0.09–0.1 M solutions of dimethyldioxirane in acetone can be obtained. A significant benefit of the new version is the fact that the originally required³⁾ amounts of peroxide reagent and buffer can be cut back to 120 g (0.195 mol) of potassium monopersulfate [the triple salt 2 KHSO₅ · KHSO₄ · K₂SO₄; trade name Curox[®] or Caroat[®]] and 58 g (0.690 mol) of NaHCO₃ to afford ca. 150 ml of a ca. 0.1 M dioxirane solution in acetone. Although the absolute yield of dioxirane is still quite low (ca. 5%), it represents a ca. threefold improvement. The optimized procedure (see below) calls for adding the caroate in five portions within 3-min intervals and distilling the dioxirane/acetone solution about 3 min after the last addition; however, satisfactory results (ca. 0.08 M in dioxirane) are also obtained when the caroate is added all at once or when the distillation is performed even as much as an hour after the last addition. Without additional instructions, laboratory technicians and beginning students had no difficulties in reproducing satisfactorily the procedure given below.

The generous gift on potassium monopersulfate from *De-gussa AG* (Hanau, Germany) and from *Peroxid-Chemie GmbH* (München, Germany), the financial support from the *Deutsche Forschungsgemeinschaft* (SFB 347 "Selektive Reaktionen Metall-akti-

vierter Moleküle") and the *Fonds der Chemischen Industrie* are gratefully appreciated.

Experimental

Procedure for the Preparation of Dimethyldioxirane in Acetone: A 4000-ml, three-necked, round-bottomed reaction flask was equipped with an efficient mechanical stirrer and an addition funnel for solids, connected by means of a U tube (i.d. 25 mm) to a two-necked receiving flask, the latter cooled at –78°C by means of a dry ice/ethanol bath. The reaction flask was charged with a mixture of water (254 ml), acetone (192 ml), and NaHCO₃ (58 g) and cooled at 5–10°C with the help of an ice/water bath. While vigorously stirring and cooling, solid caroate (120 g, 0.195 mol) was added in five portions at 3-min intervals. After 3 min of the last addition, a moderate vacuum (80–100 Torr) was applied, the cooling bath (5–10°C) removed from the reaction flask, and while vigorously stirring the dimethyldioxirane/acetone solution distilled (150 ml, 0.09–0.11 M, ca. 5% yield) and collected in the cooled (–78°C) receiving flask. The concentration of dimethyldioxirane was determined by oxidation of methyl phenyl sulfide to its sulfoxide, the latter quantified by ¹H NMR. The acetone solution of dimethyldioxirane was dried with K₂CO₃ and stored in the freezer (–20°C) over molecular sieves (4Å).
